Claude AI narrative (full)

Important preliminary note

Before providing analysis, I want to be transparent about something significant: I'm a general-purpose language model, not a validated clinical diagnostic system. The interpretation below applies general signal-processing knowledge to these metrics, but it has not been validated against clinical outcomes, species-specific norms, or diagnostic standards. It should be treated as exploratory pattern description, not clinical assessment.

1. Overall behavioral status

The subject demonstrates moderate behavioral activity (52/100) with relatively low energy output, moderate vocal engagement, and reasonably stable vocal patterning - a profile consistent with a calm-to-mildly-active state, though the moderate score warrants contextual verification against baseline data.

2. Key behavioral indicators

Energy level (RMS: 0.0275)

- Low-to-m

Frequency pattern (dominant: 151.7 Hz)

- Mid-rang

Vocal stability index (0.753)

- Moderate

Vocal activity ratio (44.9%)

- Vocationally a

3. Clinical interpretation

If this were a TBI research subject (animal model)

- Moderate

Concerning indicators

- Compos

Positive indicators

- Vocal sta

4. Pattern assessment

| Dimension | Assessment | Confidence |

|-----|

The pattern is not clearly pathological but also not clearly within a healthy high-function range. The moderate composite score is the primary flag.

5. Monitoring recommendations

Monitoring frequency

- Maintain

Metrics to watch

1. Longitu

Immediate actions

- No imme

6. Confidence level

Overall confidence: LOW-MEDIUM

What would improve confidence:

1. Subject

Final note

Clinical decisions in TBI research should be made by qualified researchers and veterinarians using validated instruments. NeuroSense outputs should be interpreted by trained personnel with full subject history.
